AQA Biology AS Level (7402) Bio6T 2015 Paper: A Deep Dive into Skeletal Muscle

The AQA Biology AS Level (7402) specification includes a significant focus on human physiology, with skeletal muscle forming a crucial component. The 2015 Bio6T paper tested students' understanding of skeletal muscle structure, function, and contraction mechanisms. This detailed guide will dissect the key concepts from that paper, helping you understand the topic thoroughly and prepare effectively for your own exams. While there aren't unique advantages specific to the 2015 paper itself, understanding its questions helps illustrate the typical exam style and content tested. The 2015 paper likely assessed candidates' ability to apply their knowledge to novel scenarios and interpret data related to skeletal muscle. This approach is common across AQA exams, emphasizing understanding over rote memorization. Let's explore the key aspects of skeletal muscle that were likely covered:

1. Skeletal Muscle From Sarcomere to Muscle Fibre

Skeletal muscle is composed of bundles of muscle fibres, each encased in a connective tissue sheath called the endomysium. These fibres are multinucleated, meaning they contain many nuclei. The crucial functional unit of skeletal muscle is the sarcomere, a repeating unit within the myofibrils, which run the length of the muscle fibre. | Sarcomere Component | Description | ||| | Actin Filaments | Thin filaments anchored at the Z-line. | | Myosin Filaments | Thick filaments with myosin heads. | | Z-line | Boundary marking the end of a sarcomere. | | M-line | Centre of the sarcomere, anchoring myosin. | | H-zone | Region containing only myosin filaments. | | I-band | Region containing only actin filaments. | | A-band | **Entire length of the myosin filaments.** | Practical Example: **Imagine a rope (muscle fibre) made of many smaller strands (myofibrils). Each strand is composed of repeating units (sarcomeres) which shorten to cause the overall rope to contract.**

2. The Sliding Filament Theory: How Muscles Contract

The sliding filament theory explains muscle contraction. It postulates that muscle contraction occurs due to the sliding of actin filaments over myosin filaments, shortening the sarcomere. This process requires ATP (adenosine triphosphate) and is regulated by calcium ions (Ca^{2+}). 1. Nerve Impulse: A nerve impulse triggers the release of acetylcholine at the neuromuscular junction. 2. Calcium Release: **This stimulates the release of Ca^{2+} from the sarcoplasmic reticulum (SR). 3.** Cross-Bridge Cycling: *Ca^{2+} binds to troponin, causing a conformational change that exposes myosin-binding sites on actin. Myosin heads bind to actin, forming cross-bridges. 4.* Power Stroke: **ATP hydrolysis provides energy for the myosin head to pivot, pulling the actin filament towards the centre of the sarcomere. 5.** Detachment:

ATP binds to the myosin head, causing detachment from actin. 6. Re-cocking: **ATP hydrolysis re-cocks the myosin head, ready for another cycle. This continues until Ca^{2+} levels decrease, and the muscle relaxes.** Practical Example: *Think of pulling a rope (actin) using your hand (myosin head). Each pull represents a power stroke, and the combined pulls shorten the rope (muscle contraction).*

3. Types of Muscle Fibres: Fast and Slow Twitch

Skeletal muscle fibres are not all the same. They can be classified into: • Fast-twitch fibres: **These contract rapidly and powerfully but fatigue quickly. They are adapted for short bursts of intense activity like sprinting. •** Slow-twitch fibres: **These contract slowly and less powerfully but are resistant to fatigue. They are adapted for endurance activities like marathon running. | Feature | Fast-twitch Fibres | Slow-twitch Fibres | |||| | Contraction Speed | Fast | Slow | | Fatigue Resistance | Low | High | | Myoglobin Content | Low | High | | Mitochondria | Few | Many | | ATP Production | Anaerobic | Aerobic |** Practical Example: **A weightlifter relies more on fast-twitch fibres for powerful lifts, while a long-distance runner relies on slow-twitch fibres for sustained effort.**

4. Muscle Metabolism and Energy Sources

Muscle contraction requires energy, primarily supplied by ATP. Different metabolic pathways provide ATP: • Creatine phosphate: *Provides a rapid source of ATP for short bursts of activity.* • Anaerobic respiration: **Provides ATP quickly but produces lactic acid, leading to muscle fatigue. •** Aerobic respiration: **Provides a sustained supply of ATP but is slower.** Practical Example: A short sprint relies heavily on creatine phosphate and anaerobic respiration, while a long-distance run relies more on aerobic respiration.

Conclusion

Understanding skeletal muscle structure, function, and contraction mechanisms is crucial for success in AQA Biology AS Level. The 2015 Bio6T paper likely tested your understanding of these concepts, potentially through data interpretation, application questions, and scenario-based problems. By mastering the fundamental principles detailed above, you will be well-equipped to tackle similar questions in future exams.

FAQs

1. What is the difference between isometric and isotonic contractions? *Isometric contractions involve muscle tension without shortening (e.g., holding a weight), while isotonic contractions involve muscle shortening with constant tension (e.g., lifting a weight). 2.* How does muscle fatigue occur? Muscle fatigue is caused by the depletion of ATP, accumulation of lactic acid, and electrolyte imbalances. 3. What is the role of the neuromuscular junction? **The neuromuscular junction is the site where a motor neuron releases acetylcholine to stimulate muscle contraction. 4.** How do muscle fibres regenerate? **Muscle fibres have limited regenerative capacity, primarily relying on satellite cells for repair. 5.** What are the different types of muscle tissue?** There are three types: skeletal muscle (voluntary, striated), smooth muscle (involuntary, non-striated), and cardiac muscle (involuntary, striated).

Unpacking the AQA BIO6T 2015 Paper: A Deep Dive into Skeletal Muscle

Ah, the AQA BIO6T 2015 paper! For many biology students, this exam session, particularly the questions surrounding skeletal muscle, might still bring back a flicker of memory – perhaps a mix of intense revision and the exhilaration (or trepidation!) of facing those challenging questions. As a content writer who loves delving into the intricacies of biology, I find that dissecting past papers like this is not just an academic exercise; it’s a fascinating way to understand how complex biological concepts are assessed and to highlight the enduring importance of topics like skeletal muscle physiology.

Skeletal muscle is a cornerstone of vertebrate anatomy and physiology. It's responsible for our movement, our posture, and even plays a role in our metabolism. So, it's no surprise that it features prominently in advanced biology exams. This article aims to provide a comprehensive overview of what a student might have encountered regarding skeletal muscle in the AQA BIO6T 2015 paper, offering insights into the key concepts, potential question areas, and the underlying biological principles. Whether you're a student preparing for future exams, a teacher looking for material, or simply a biology enthusiast, let's get ready to flex our understanding of skeletal muscle!

The Building Blocks: Sarcomeres and Myofibrils

Any discussion of skeletal muscle begins with its fundamental unit: the sarcomere. These highly organized structures are the powerhouses within muscle cells, responsible for generating force. The 2015 paper would undoubtedly have expected students to have a solid grasp of the sarcomere's architecture. This includes understanding the roles of the:

1. **Actin and Myosin Filaments:** These are the contractile proteins. Myosin filaments are thick, with bulbous heads that interact with actin. Actin filaments are thin and have binding sites for the myosin heads. The precise arrangement of these filaments, creating the characteristic banding patterns (A bands, I bands, Z lines), is crucial.
2. **Z Lines:** These delineate the boundaries of each sarcomere.
3. **M Line:** Located in the center of the sarcomere, anchoring the myosin filaments.
4. **H Zone:** The region within the A band where there is no overlap between actin and myosin filaments in a relaxed state.

Students would also need to understand that these sarcomeres are arranged end-to-end within myofibrils, which are the long, cylindrical organelles that make up the bulk of a muscle fiber (muscle cell). The striations visible under a microscope are a direct consequence of this highly ordered sarcomere structure.

The Sliding Filament Theory: How Muscles Contract

The mechanism of muscle contraction, famously explained by the sliding filament theory, is a central theme. The AQA BIO6T 2015 paper likely tested a detailed understanding of this process, often requiring students to explain it in a step-by-step manner. Here’s a breakdown of what would be expected:

1. **Resting State:** In a relaxed muscle, the myosin binding sites on actin are blocked by tropomyosin, a protein that is regulated by troponin.

2. **Arrival of the Nerve Impulse:** A motor neuron transmits an action potential to the neuromuscular junction. This triggers the release of acetylcholine, a neurotransmitter.
3. **Excitation-Contraction Coupling:** Acetylcholine binds to receptors on the muscle fiber membrane (sarcolemma), causing depolarization. This depolarization travels down the T-tubules, which are invaginations of the sarcolemma. This triggers the release of calcium ions (Ca^{2+}) from the sarcoplasmic reticulum.
4. **Calcium's Role:** Calcium ions bind to troponin. This causes a conformational change in troponin, which in turn moves tropomyosin away from the myosin-binding sites on actin.
5. **Cross-Bridge Formation and Cycling:** With the binding sites exposed, the myosin heads can bind to actin, forming cross-bridges. ATP binds to the myosin head, causing it to detach from actin and re-energize (hydrolyze ATP to ADP and Pi). The myosin head then cocks into a high-energy position. When calcium is present, the myosin head can reattach to actin, forming a new cross-bridge. The release of Pi then triggers the power stroke, where the myosin head pulls the actin filament towards the center of the sarcomere, shortening the sarcomere.
6. **Relaxation:** For the muscle to relax, the nerve impulse must stop. Calcium ions are actively pumped back into the sarcoplasmic reticulum, requiring ATP. As calcium levels drop, tropomyosin returns to block the myosin-binding sites on actin, and cross-bridge cycling ceases.

Questions could have involved describing the role of ATP at various stages, the importance of calcium ions, or the differences between a contracted and a relaxed sarcomere.

Energy for Contraction: ATP and its Regeneration

Muscle contraction is an energy-intensive process. The AQA BIO6T 2015 paper would have probed students' knowledge of how muscle cells generate and regenerate ATP. This typically involves understanding several interconnected systems:

1. **Direct Phosphorylation (Creatine Phosphate System):** This is the quickest way to resynthesize ATP. Creatine phosphate (CP) donates a phosphate group to ADP, forming ATP. This system provides energy for very short bursts of intense activity, lasting only a few seconds.
2. **Anaerobic Respiration (Glycolysis):** When ATP demand exceeds the rate of creatine phosphate regeneration, muscles turn to glycolysis. Glucose is broken down into pyruvate, producing a small amount of ATP. In the absence of sufficient oxygen, pyruvate is converted to lactic acid. This process is rapid but inefficient and leads to a buildup of lactic acid, causing muscle fatigue.
3. **Aerobic Respiration:** This is the most efficient way to produce ATP, occurring in the mitochondria. Pyruvate (from glycolysis) enters the Krebs cycle and then the electron transport chain, utilizing oxygen to produce a large amount of ATP. This system is sustainable for prolonged periods of moderate activity but is slower to initiate than the other two.

Students might have been asked to compare and contrast these energy systems, explain their relative speeds and efficiencies, or describe the conditions under which each system is primarily used. The concept of oxygen debt, which arises from anaerobic respiration, would also be a likely area of assessment.

Neuromuscular Junction: The Command Center

The link between the nervous system and skeletal muscle is the neuromuscular junction (NMJ).

Understanding its structure and function is vital. Key aspects include:

1. **Motor Neuron and Muscle Fiber:** The NMJ is the synapse between the axon terminal of a motor neuron and the motor end plate of a muscle fiber.
2. **Neurotransmitter Release:** Action potential arriving at the axon terminal causes voltage-gated calcium channels to open, leading to influx of Ca^{2+}. This triggers the exocytosis of acetylcholine (ACh) into the synaptic cleft.
3. **ACh Receptors:** ACh diffuses across the synaptic cleft and binds to nicotinic acetylcholine receptors on the motor end plate.
4. **Depolarization and Action Potential:** This binding opens ligand-gated ion channels, allowing Na^{+} to enter the muscle fiber, causing depolarization and initiating an action potential along the sarcolemma and T-tubules.
5. **Acetylcholinesterase:** The enzyme acetylcholinesterase breaks down ACh in the synaptic cleft, ensuring that the muscle fiber is only stimulated briefly and preventing continuous contraction.

Questions could have focused on the events at the NMJ, the role of specific molecules like acetylcholine and acetylcholinesterase, or the consequences of disruptions at this junction.

Types of Muscle Fibers: Fast-Twitch vs. Slow-Twitch

Not all skeletal muscle fibers are created equal. The AQA BIO6T 2015 paper might have explored the different types of muscle fibers and their adaptations for specific functions. The two main categories are:

1. **Slow-Twitch (Type I) Fibers:** These are adapted for endurance activities. They are rich in mitochondria, have a high myoglobin content (giving them a red appearance and facilitating oxygen diffusion), and rely heavily on aerobic respiration. They contract relatively slowly but are highly resistant to fatigue.
2. **Fast-Twitch (Type II) Fibers:** These are adapted for powerful, rapid contractions. They have fewer mitochondria, lower myoglobin content, and rely more on anaerobic respiration. They fatigue more quickly but can generate a lot of force. There are further subdivisions of fast-twitch fibers (e.g., Type IIa and Type IIb/x) with varying characteristics.

Students might have been asked to compare the structural and functional differences, link fiber types to specific sports or activities, or explain how training can influence fiber type characteristics (though the extent of plasticity is debated).

Factors Affecting Muscle Function

Beyond the fundamental mechanisms, the paper could have touched upon various factors that influence skeletal muscle performance. These might include:

1. **Muscle Fatigue:** Understanding the causes of muscle fatigue is crucial. This can include the depletion of ATP and glycogen stores, the accumulation of metabolic byproducts like lactic acid and inorganic phosphate, and the impairment of calcium release and reuptake.
2. **Muscle Strength and Endurance:** These are influenced by factors such as the size of the muscle, the number of motor units recruited, the frequency of stimulation, and the type of muscle fibers present.
3. **Temperature:** Optimal temperature ranges exist for enzyme activity involved in muscle contraction

and energy production.
4. **Oxygen Availability:** As discussed, oxygen is critical for efficient ATP regeneration through aerobic respiration.

Answering AQA BIO6T Questions: Strategies for Success

When approaching questions on skeletal muscle, like those from the AQA BIO6T 2015 paper, a structured approach is key:

1. **Read Carefully:** Understand exactly what the question is asking. Are they asking for a description, a comparison, an explanation, or an evaluation?
2. **Use Precise Terminology:** Biology exams require accurate use of scientific terms. Ensure you're using terms like sarcomere, myofibril, actin, myosin, ATP, acetylcholine, sarcoplasmic reticulum, etc., correctly.
3. **Draw Diagrams (When Appropriate):** A well-labelled diagram of a sarcomere or the sliding filament theory can significantly enhance your answer and demonstrate understanding.
4. **Explain Processes Step-by-Step:** For questions on muscle contraction or energy regeneration, breaking down the process into clear, logical steps is essential.
5. **Link Structure and Function:** Always try to connect the structural features of muscle cells and their components to their specific functions.
6. **Consider the "Why":** Beyond just stating what happens, try to explain why it happens – what is the biological advantage or necessity of a particular mechanism?

Unpacking the AQA Bio6T 2015 Paper: A Deep Dive into Skeletal Muscle Physiology

The AQA Biology Unit 6T (Legacy A-Level Syllabus) paper from 2015 remains a significant reference point for understanding the assessment of complex biological concepts. Among its challenging topics, skeletal muscle physiology consistently features prominently, demanding a thorough grasp of its intricate structure, function, and regulation. This article provides a detailed, analytical breakdown of the skeletal muscle-related questions from the AQA Bio6T 2015 paper, aiming to equip students and educators with a deeper understanding of key concepts, common pitfalls, and strategies for excelling in future examinations. We'll explore the microscopic architecture, the molecular mechanisms of contraction, and the physiological factors influencing muscle performance, all through the lens of this specific past paper.

The Microscopic Canvas: Sarcomere Structure and its Role in Contraction

A cornerstone of skeletal muscle physiology is the sarcomere, the fundamental contractile unit. The 2015 Bio6T paper likely probed students' understanding of the sarcomere's highly organised structure, comprising repeating units of actin (thin filaments) and myosin (thick filaments). Key components that would have been assessed include:

1. **Z-lines:** These define the boundaries of each sarcomere and serve as anchor points for actin filaments.
2. **I-band:** The region containing only actin filaments. Its width changes during contraction.
3. **A-band:** The region containing the entire length of the myosin filaments, overlapping with actin. Its width remains constant during contraction.
4. **H-zone:** The central region of the A-band containing only myosin filaments. This zone shortens significantly during contraction.
5. **M-line:** Located in the center of the H-zone, this anchors myosin filaments.

Understanding how these bands and zones change (or don't change) during muscle contraction is crucial. The sliding filament theory, a central tenet of muscle physiology, explains this phenomenon. The AQA

Bio6T 2015 paper would have assessed the ability to describe this process, likely involving the interaction between myosin heads and actin binding sites, powered by ATP. Keywords such as **actin-myosin cross-bridges**, **power stroke**, and the role of **troponin** and **tropomyosin** in regulating this interaction would have been vital.

Understanding Sliding Filament Theory: A Step-by-Step Analysis

For a robust answer regarding skeletal muscle contraction, students would need to articulate the sliding filament theory comprehensively. This involves:

1. **Initiation of Contraction:** The arrival of an action potential at the neuromuscular junction triggers the release of acetylcholine, leading to depolarization of the muscle fiber membrane (sarcolemma). This electrical signal propagates down T-tubules.
2. **Calcium Release:** The depolarization of T-tubules causes the sarcoplasmic reticulum (SR) to release stored calcium ions (Ca^{2+}) into the sarcoplasm.
3. **Troponin-Tropomyosin Complex:** In a resting muscle, troponin-tropomyosin complex blocks the myosin-binding sites on actin.
4. **Calcium Binding:** Ca^{2+} ions bind to troponin, causing a conformational change in the troponin-tropomyosin complex. This exposes the myosin-binding sites on actin.
5. **Cross-Bridge Formation:** Energized myosin heads (bound to ADP and Pi) attach to the exposed binding sites on actin, forming cross-bridges.
6. **Power Stroke:** The release of ADP and Pi from the myosin head causes it to pivot, pulling the actin filament towards the M-line. This is the power stroke.
7. **ATP Binding and Detachment:** A new ATP molecule binds to the myosin head, causing it to detach from actin.
8. **ATP Hydrolysis and Re-energization:** ATP is hydrolyzed to ADP and Pi, re-energizing the myosin head and returning it to its high-energy conformation, ready for another cycle.
9. **Sarcomere Shortening:** This cycle of cross-bridge formation, power stroke, and detachment repeats, causing the actin filaments to slide past the myosin filaments, shortening the sarcomere and thus the entire muscle fiber.

Examining the 2015 paper's questions would reveal how effectively students could translate this theoretical knowledge into a structured, detailed explanation, demonstrating their understanding of the molecular players and their orchestrated movements. The ability to link microscopic events to macroscopic muscle shortening is a hallmark of a strong understanding of muscle physiology.

Energy for Contraction: The Crucial Role of ATP and Cellular Respiration

Muscle contraction is an energetically demanding process. The AQA Bio6T 2015 paper would have undoubtedly tested students' knowledge of the various energy systems supporting skeletal muscle function. ATP is the immediate energy currency, but its supply needs to be replenished rapidly. Key energy sources and pathways include:

1. **Immediate ATP Stores:** A small, readily available pool of ATP within muscle cells, sufficient for a few seconds of maximal activity.

2. **Creatine Phosphate System:** This system rapidly regenerates ATP from ADP using phosphate from creatine phosphate. It provides energy for short bursts of intense activity (up to ~10 seconds). The equation **ADP + creatine phosphate → ATP + creatine** is fundamental here.
3. **Anaerobic Respiration (Glycolysis):** The breakdown of glucose in the absence of oxygen produces ATP and lactic acid. This is a faster, but less efficient, ATP production method, sustaining activity for a few minutes. Understanding the accumulation of **lactic acid** and its role in muscle fatigue is crucial.
4. **Aerobic Respiration:** The complete oxidation of glucose (and other substrates like fatty acids) in the presence of oxygen, producing a large amount of ATP through the Krebs cycle and oxidative phosphorylation. This is the primary energy source for sustained, moderate-intensity activity. The role of **mitochondria** and the availability of **oxygen** are paramount.

Questions might have involved comparing the efficiency and duration of these energy systems, or calculating ATP production under different physiological conditions. Understanding the interplay between these systems, and how the body switches between them based on exercise intensity and duration, would have been a key assessment objective. Furthermore, the impact of insufficient oxygen supply (hypoxia) on energy production and the subsequent onset of anaerobic respiration and lactic acid buildup are critical aspects of muscle physiology that the 2015 paper likely explored.

Regulation of Muscle Contraction: Neural Control and Signal Transduction

Skeletal muscles are under voluntary control, meaning their contraction is initiated by signals from the nervous system. The 2015 Bio6T paper would have assessed the understanding of:

1. **Neuromuscular Junction (NMJ):** The specialized synapse where a motor neuron communicates with a muscle fiber. This involves the release of the neurotransmitter **acetylcholine**, binding to receptors on the muscle fiber sarcolemma, and triggering depolarization.
2. **Motor Unit:** A single motor neuron and all the muscle fibers it innervates. The size of a motor unit influences the precision of muscle control.
3. **Recruitment of Motor Units:** The nervous system controls muscle force by recruiting different numbers of motor units. Smaller motor units (innervating fewer, slow-twitch fibers) are recruited first for fine motor movements, while larger motor units (innervating more, fast-twitch fibers) are recruited for powerful contractions.
4. **Frequency of Stimulation (Summation and Tetanus):** The rate at which a motor neuron fires action potentials affects the strength of muscle contraction. **Summation** occurs when a second stimulus arrives before the muscle has fully relaxed from the first, leading to a stronger contraction. **Tetanus** is a sustained, maximal contraction resulting from very high-frequency stimulation, where individual twitches fuse together.

The paper might have presented scenarios requiring students to explain how the nervous system fine-tunes muscle force, or how different types of muscle fibers (e.g., slow-twitch vs. fast-twitch) are recruited for different activities. Understanding the electrical signaling processes from neuron to muscle, including the role of ion channels and membrane potentials, would have been essential.

Factors Affecting Muscle Performance and Fatigue

Beyond the fundamental mechanisms, the AQA Bio6T 2015 paper likely delved into factors that influence muscle strength, endurance, and the phenomenon of fatigue. These include:

1. **Muscle Fiber Type:** As mentioned, the proportion of slow-twitch and fast-twitch fibers in a muscle influences its capacity for endurance and power. Slow-twitch fibers are rich in mitochondria and myoglobin, suited for aerobic respiration and sustained contractions, while fast-twitch fibers have more glycogen stores and enzymes for anaerobic respiration, suited for rapid, powerful bursts.
2. **Muscle Length:** The force a muscle can generate is dependent on its length. There is an optimal length where the overlap between actin and myosin filaments is maximized, leading to the greatest number of cross-bridges.
3. **Muscle Temperature:** Increased muscle temperature generally enhances enzyme activity and nerve conduction, leading to improved performance.
4. **Muscle Fatigue:** This is a complex phenomenon with multiple contributing factors. Common causes include depletion of energy stores (ATP, glycogen), accumulation of metabolic byproducts (lactic acid, inorganic phosphate), and disruptions in ion balance (particularly calcium). Central fatigue, originating in the central nervous system, can also play a role.

Questions related to these factors would require students to synthesize their knowledge of underlying physiological processes. For instance, explaining how inadequate oxygen supply during prolonged strenuous exercise leads to lactic acid accumulation and subsequently contributes to muscle fatigue would be a comprehensive answer. The ability to differentiate between causes of fatigue during short, intense exercise versus prolonged, moderate exercise would also be a mark of a well-rounded understanding.

Questions & Answers About aqa bio6t 2015 paper skeletal

muscle

No	Question	Answer
1	What were the key adaptations of skeletal muscle highlighted in the AQA BioT 2015 paper, and why are they important for function?	The paper likely focused on sarcoplasmic reticulum's role in calcium storage and release for contraction, abundant mitochondria for ATP production to fuel muscle activity, and the sarcoplasmic reticulum's extensive network for rapid ion diffusion. These are crucial for efficient and sustained muscle contraction.
2	How did the 2015 paper explain the sliding filament theory of muscle contraction, and what were the essential protein interactions involved?	The AQA BioT 2015 paper would have detailed the sliding filament theory, emphasizing the interaction between actin and myosin filaments. Myosin heads bind to actin, pull them inwards, and detach, powered by ATP hydrolysis, causing the sarcomere to shorten.
3	What role did ATP play in skeletal muscle contraction according to the 2015 AQA BioT paper, and where was it utilized?	ATP is vital for muscle contraction. It provides the energy for myosin head detachment from actin, powers the re-uptake of calcium ions into the sarcoplasmic reticulum, and fuels the sodium-potassium pump for restoring ion gradients.
4	Did the AQA BioT 2015 paper discuss different types of muscle fibres (e.g., slow-twitch vs. fast-twitch)? If so, what are their main distinguishing features?	Yes, the paper likely differentiated between slow-twitch (Type I) and fast-twitch (Type II) fibres. Slow-twitch fibres are rich in mitochondria and myoglobin, suited for endurance. Fast-twitch fibres have fewer mitochondria but higher glycogen stores, enabling powerful, rapid contractions.
5	What mechanisms for regulating skeletal muscle contraction were likely covered in the 2015 paper, beyond the basic sliding filament model?	Regulation would have included the role of the nervous system (neuromuscular junction, action potentials), calcium ions as a key intracellular messenger, and the involvement of troponin and tropomyosin in controlling actin-myosin binding.
6	Were any aspects of muscle fatigue or its causes discussed in the AQA BioT 2015 paper regarding skeletal muscle?	The paper might have touched upon muscle fatigue, attributing it to factors such as depletion of ATP and glycogen stores, accumulation of metabolic byproducts like lactic acid, and impaired calcium ion release or re-uptake.
7	How did the 2015 AQA BioT paper link the structure of skeletal muscle (e.g., sarcomeres, myofibrils) to its contractile function?	The paper would have explained that the highly organised structure of myofibrils, composed of repeating sarcomeres with overlapping actin and myosin filaments, allows for the coordinated shortening of the muscle. This arrangement is directly responsible for generating force and movement.
